Computer Science 162 Sam Kumar University of California, Berkeley Quiz 2 July 20, 2020

Name	
Student ID	

This is an open-book exam. You may access existing materials, including online materials (such as the course website). During the quiz, you may **not** communicate with other people regarding the quiz questions or answers in any capacity. For example, posting to a forum asking for help is prohibited, as is sharing your exam questions or answers with other people (or soliciting this information from them).

You have 80 minutes to complete it. If there is something in a question that you believe is open to interpretation, please make a private post on Piazza asking for clarification. If you run into technical issues during the quiz, join our open Zoom call and we will try to help you out. The final page is for reference.

We will overlook minor syntax errors in grading coding questions. You do not have to add the necessary #include statements at the top.

Grade Table (for instructor use only)

Question:	1	2	3	4	5	6	Total
Points:	1	10	25	20	24	0	80
Score:							

1.	(1 point) Please check the boxes next to the following statements after you have read through and agreed with them.
	\square I will complete this quiz with integrity, doing the work entirely on my own.
	\square I will NOT attempt to obtain answers or partial answers from any other people.
	$\hfill\square$ I will NOT post questions about this quiz on online platforms such as StackOverflow.
	\square I will NOT discuss any information about this quiz until 24 hours after it is over.
	☐ I understand the consequences of violating UC Berkeley's Code of Student Conduct.

2. (10 points) Operating System Concepts

O False

Choose either True or False for the questions below. You do not need to provide justifications. Each student received 10 questions, chosen randomly from the ones below.

(a)	(1 point)	A successful call to pthread_create always issues a system call. True
	\bigcirc	False
(b)	(1 point)	A successful call to pthread_mutex_lock always issues a system call. True False
(c)	. – ,	It is possible to implement a mutex in userspace for kernel-provided threads (e.g.,) that never issues a system call and never busy-waits. True False
(d)	(1 point) disabled.	It is impossible for the kernel to switch to another thread while interrupts are
	0	True False
(e)	` - /	It is possible to implement a lock using only semaphores (with no other calls to terrupts, acquire locks, use condition variables, or issue atomic read-modify-write ons).
	0	True False
(f)	other call	It is possible to implement a condition variable using only semaphores (with no ls to disable interrupts, acquire locks, use condition variables, or issue atomic ify-write instructions).
	0	True
	\bigcirc	False
(g)	, – ,	If two threads belonging to the same process concurrently issue a read system out proper synchronization in user space, kernel data structures may become l.
		True
	\bigcirc	False
(h)	(1 point) chine.	SRTF is an optimal solution to hard real-time scheduling on a single-core ma-
	\bigcirc	True
		False
(i)	` - /	It is possible to implement scheduling algorithms like MLFQ using a priority, by dynamically adjusting the priorities of threads.
	\bigcirc	True

(j)		In Pintos, the struct thread representing a user process is <i>always</i> stored on page as the thread's user stack.
	\bigcirc	True
	\bigcirc	False
(k)	(- /	In Pintos, the \mathtt{struct} thread representing a user process is always stored on page as the thread's kernel stack.
	\bigcirc	True
	\bigcirc	False
(1)	(1 point) well-cond	In general, a web server that spawns a new process to handle each request is itioned.
	\bigcirc	True
	\bigcirc	False
(m)	(1 point) lock.	Modern operating systems, like Linux, use Banker's Algorithm to avoid dead-
	\bigcirc	True
	\circ	False
(n)	. – ,	In Stride Scheduling, a job with a lower stride is given more CPU time than a higher stride, on average.
	\bigcirc	True
		False
(o)	(- /	Priority donation solves the priority inversion problem by allowing a high priority take a lock away from a low priority thread before the low priority thread releases
	\bigcirc	True
	\bigcirc	False

3. (25 points) Short Answer

Answer the following questions. Each student received 7 questions, taken from the ones below as follows: one of a or b, one of c or d, one of e or f, one of h or i, one of j or k, and g and l.

(a) (4 points) The CS 162 TAs set up a search engine service, similar to Google. They measured that, on average, the system is able to process 100 requests per second, and that the average latency for each request is 162 ms. On average, how many requests are being processed by the system at any given instant? Explain.
(b) (4 points) List three techniques to reduce context switch overhead in a highly concurrent system.

(c) (3 points) How can the kernel synchronize access to data shared by a thread and an interrupt handler?

(d) (3 points) How can a user program synchronize access to data shared by a thread and s

(d) (3 points) How can a user program synchronize access to data shared by a thread and a signal handler?

(e) (4 points) Is there ever a situation where busy-waiting is more efficient than putting a thread to sleep and waking it up with an interrupt? List such a situation, or explain why

	none exists.
(f)	(4 points) Why might finer-grained locking lead to improved performance?
(g)	<pre>(4 points) Consider the following code to acquire a spin-lock: void wait_until_two_then_increment(int* var) { while (!compare_and_swap(var, 2, 3)) {} }</pre>
	Modify the the wait_until_two_then_increment function to busy-wait more efficiently. Write your new implementation of the function below. It should continue to busy-wait; do not suspend the calling thread. Hint: compare_and_swap is an atomic read-modify-write instruction. compare_and_swap(var, 2, 3) atomically: (1 returns the value of *var == 2 and (2) if it returns true, it sets *var = 3.
(h)	(3 points) In what sense is EDF optimal?
<i>(</i> .)	

(i) (3 points) In what sense is SRTF optimal?

- (j) (3 points) Explain how MLFQ maintains responsiveness of interactive tasks.
- (k) (3 points) Under which metric does FCFS outperform round robin?

(l) (4 points) For each of the three scheduling metrics we discussed in class—throughput, timeliness, and fairness—explain how Linux CFS caters to each one.

4. (20 points) Deadlock and Scheduling

Consider the following C program.

```
pthread_mutex_t x, y, z;
void* a(void* arg) {
    pthread_mutex_lock(&y);
    pthread_mutex_lock(&z);
    pthread_mutex_unlock(&y);
    pthread_mutex_unlock(&z);
    return NULL;
}
void* b(void* arg) {
    pthread_mutex_lock(&z);
    pthread_mutex_lock(&x);
    pthread_mutex_unlock(&z);
    pthread_mutex_unlock(&x);
    return NULL;
}
void* c(void* arg) {
    pthread_mutex_lock(&x);
    pthread_mutex_lock(&y);
    pthread_mutex_unlock(&x);
    pthread_mutex_unlock(&y);
    return NULL;
}
int main(int argc, char** argv) {
    pthread_mutex_init(&x, NULL);
    pthread_mutex_init(&y, NULL);
    pthread_mutex_init(&z, NULL);
    pthread_t a_thread, b_thread, c_thread;
    pthread_create(&a_thread, NULL, a, NULL);
    pthread_create(&b_thread, NULL, b, NULL);
    pthread_create(&c_thread, NULL, c, NULL);
    pthread_join(&a_thread, NULL);
    pthread_join(&b_thread, NULL);
    pthread_join(&c_thread, NULL);
    return 0;
}
```

(a) (3 points) Provide a valid execution order that results in deadlock. By execution order, we mean the sequence in which threads acquire and release locks. Provide your answer as a list of statements of the form "THREAD calls lock_acquire(LOCK)" or "THREAD calls lock_release(LOCK)" (where THREAD is one of a, b, or c and LOCK is one of x, y, or z"). Include calls to lock_acquire that block.

(e) (3 points) Would using a preemptive thread scheduler eliminate the possibility of dead-

lock?

(f)	(4 points) A student in CS 162 attempts to fix the above code, so that it is deadlock-free regardless of the scheduler, by rewriting the function c as follows:
	regardless of the scheduler, by rewriting the function c as follows.
	<pre>void* c(void* arg) {</pre>
	<pre>pthread_mutex_lock(&y);</pre>
	<pre>pthread_mutex_lock(&x);</pre>
	<pre>pthread_mutex_unlock(&x);</pre>
	<pre>pthread_mutex_unlock(&y);</pre>
	return NULL;
	}
	Is the resulting code deadlock-free? If not, provide an execution order that results in
	deadlock. If so, explain why the program is deadlock-free.

5. (24 points) Single Shared Pipe

Bobby, William, Jonathan, and Kevin are in a group for their CS 162 project, and they have just finished Project 1. Bobby, being an eager student, wants to extend Pintos by adding additional support for inter-process communication (IPC).

(a) (3 points) William suggests adding a pipe system call to Pintos. It would work the same way as in Linux; a pipe is created in the kernel, and the calling process obtains read and write file descriptors to access the pipe. What else must be implemented in Pintos to use a pipe for communication between two different processes?

- 1				
- 1				

(b) (3 points) Jonathan suggests implementing sockets in Pintos. Sockets would use the same APIs as in Linux. Would using sockets for communication between two *different* processes require the same change you identified in the previous part? Explain why or why not.

(c) (18 points) Kevin suggests modifying the pipe abstraction so that it can be used for IPC in Pintos. Instead of there being a pipe system call to create a pipe, there exists a single global pipe shared by all processes in the system. Any process can write a byte into the pipe by issuing a pipe_write system call, and any process can read a byte from the pipe by issuing a pipe_read system call. The interface to the system calls is as follows:

```
/* Writes the byte BYTE to the pipe. */
void pipe_write(uint8_t byte);

/* Reads a byte from the pipe and returns it. */
uint8_t pipe_read();
```

The pipe has the same semantics as a pipe in Linux. In particular:

- If the pipe is full, writes block until space is available to complete the write.
- If the pipe is empty, reads block until data is written to the pipe.
- No data should be read from the pipe twice; once one process reads data from the pipe, that data is no longer in the pipe and cannot be read by other processes.

In principle, the capacity of the pipe could be any nonnegative number of bytes. For the purpose of this question, the capacity of the pipe should be 162.

You may wish to look at all parts of this question first, before starting to answer it. If you believe that no code is needed for one or more parts of this question, it is fine to just leave those sections of the code blank. If you wish, you may write "NO CODE" in the appropriate code blocks for clarity.

As part of implementing Project 1, Bobby implemented the following useful functions: void validate_user_buffer(void* pointer, size_t length); void validate_user_string(const char* string);

These functions check if the provided buffer (or string) exists entirely within valid user-accessible memory. If not, they terminate the calling process with exit code -1.

i. Implement the system call handler for the pipe_write and pipe_read syscalls below. You may make calls to validate_user_buffer and/or validate_user_string. You may not need all of the blank lines.

```
static void syscall_handler (struct intr_frame* f) {
    uint32_t* args = ((uint32_t*) f->esp);
    validate_user_buffer(args, sizeof(uint32_t));
    switch (args[0]) {
        /* Pre-existing cases (not shown) */
    case SYS_PIPE_WRITE:
        syscall_pipe_write((uint8_t) args[1]);
        break;
    case SYS_PIPE_READ:
        f->eax = (uint32_t) syscall_pipe_read();
        break;
        /* Additional pre-existing cases (not shown) */
    }
}
```

ii.	may	no uct	t nee thre	d to use all o ead {	d struct thr of the blank li nembers (not	nes.		's IPC functionality.	You

6. (0 points) Optional Questions

(a) (0 points) Having finished the exam, how do you feel about it? Check all that apply:

(b) (0 points) If there's anything you'd like to tell the course staff (e.g., feedback about the class or exam, suspicious activity during the exam, new logo suggestions, etc.) you can write it on this page.

```
int pthread_create(pthread_t *thread, const pthread_attr_t *attr,
                        void *(*start_routine) (void *), void *arg);
int pthread_join(pthread_t thread, void **retval);
int pthread_mutex_init(pthread_mutex_t *restrict mutex,
   const pthread_mutexattr_t *restrict attr);
int pthread_mutex_lock(pthread_mutex_t *mutex);
int pthread_mutex_unlock(pthread_mutex_t *mutex);
int pthread_cond_init(pthread_cond_t *cond, pthread_condattr_t *cond_attr);
int pthread_cond_signal(pthread_cond_t *cond);
int pthread_cond_broadcast(pthread_cond_t *cond);
